Q.What is the difference between 'Where' and 'Having 'clause?

- Where clause is used in row operations and it is generally applied on a single row only whereas Having clause is used in column operations and it is generally applied on summarized data and groups.
- In where clause, the desired data is fetched according to the applied condition. In contrast, having clause fetches the whole data then separation is made based on the condition.
- Aggregate functions like min, max, avg, sum, the count can never appear with Where clause while all of these can be used along Having Clause.
- We cannot use the Having Clause without a SELECT statement. Conversely, we can use Where clause with SELECT, Update or Delete statements.
- Where clause usually behaves as the pre-filter while having clause behaves like a post-filter.
